

A **distribution pool** spans a number of **projects**

Each project
decides in-
dependently
what to
produce and
how to
produce it

But all
projects
share the
same **task**
and
product
auctioning
systems

The *summed cost of the products* you want is the *effort* you have to contribute to the **distribution pool**, by doing *any tasks of your choice* from the **task auctioning system**.

The products I want to have cost 20 weighted hours.
Now, which tasks would I like to do (for which projects)?
